

Clustering of Rice Genotypes - A Multivariate Approach

D Chinni, Sk Nafeez Umar, V Srinivasa Rao and D Ratna Babu

Department of Statistics and Computer Applications, Agricultural College, Bapatla.

ABSTRACT

An important step in plant breeding programs is identification of parents that are genetically distant from each other, to find crossing combinations with better prospects of hybrid vigor. The potential of identifying genetically distant parents depends on genetic diversity of population. 60 Rice genotypes from diverse origins have been employed to study genetic variation in order to identify the most effective components of grain yield. Using cluster analysis, the genotypes were grouped into 8 clusters of which clusters II was the largest cluster consisting of 21 genotypes while cluster III, IV, VII and VIII are the smallest clusters with only a single genotype each. The maximum intra cluster distance (D = 371.74) was found in cluster VI consisting of 8 genotypes NLR 33358, ADT 45, ADT 37, JGL 1118, IR 10F221, NLR 3367, IR 64197 and ADT 43. From the inter cluster D² values of eight clusters, it can be seen that the highest divergence occurred between cluster V and cluster VI (1651.37) While the minimum inter cluster distance was noticed between cluster IV and cluster VII (94.06). Out of 17 characters studied the maximum contribution (79.66 %) towards total divergence is by 5 characters only. They are days to maturity, test weight, flag leaf width, flag leaf length, Days to 50% flowering. These characters should be taken into consideration while selecting parents for hybridization.

Key words: Genotypes, Genetic diversity, Cluster analysis, Mahalanobis D²

Rice (*Oryza sativa* L.) is the most important cereal food crop in the world providing food to over 75 % of Asian population and more than three billion of world population which represents 50 to 80 % of their daily calorie intake (Khush, 2005) and 55% of the protein intake in their average daily diet and aptly describes the slogan "Rice is life". Next to China, India is the second largest producer and consumer of rice. For meeting the dietary requirements of increasing population, genetic improvement of rice with higher yield, good grain quality, resistance to biotic and abiotic stresses is the most logical and promising approach. Genetic improvement mainly depends upon inclusion of genetically diverse parents having wider variability for different yield and quality characters in hybridization program. The more diverse the parents, the higher are the chances of obtaining more amounts of heterotic expression in F₁ and superior recombinants in the segregating generations. A lack of diversity in germplasm limits long-term progress in plant breeding. The level of genetic diversity that characterizes commercially important crops is a matter of considerable concern, as it is generally agreed that access to genetic diversity has been and remains important in maintaining and increasing agricultural productivity (Ahmadikhah, 2006). Therefore, the genetic diversity is the basis of plant breeding. Plant breeders use the present diversity in plant populations and varieties to develop new varieties or to transmit the desirable traits into undesirable varieties (De et al., 1992). Significant emphasis is being paid to comprehensive analysis of genetic diversity in numerous field crops for long-term success of breeding program and maximum exploitation of the genetic resources (Belaj *et al.*, 2002).

MATERIAL AND METHODS

A secondary data which is relevant to the study was collected from Agricultural Research Station(ARS), Nellore, Andhra Pradesh, at which experiment was carried out on 60 rice genotypes and the data was collected on yield and yield attributes viz., 50 % flowering, days to maturity, Plant height, Panicle length, flag leaf length, flag leaf width, flag leaf area, productive tillers, filled grains/panicle, ill filled grains/panicle, SCMR (SPAD Chlorophyll meter reading), plant yield, Test weight, Grain length, Grain width, grain 1/b ratio and Harvest index, during early *kharif*, 2016.

The present investigation aimed to assess the nature and magnitude of genetic divergence present in the 60 rice genotypes and to select suitable diverse genotypes as parents for further utilization in grain yield improvement programs. Genetic diversity analysis was done following D^2 statistics proposed by Mahalanobis (1936). The varieties were classified into a number of clusters by Toucher's method as described by Rao (1952). Statistical analysis for the above characters were done by using INDOSTAT software.

RESULTS AND DISCUSSION

ANOVA showed that the studied genotypes had significantly differences in all traits. The betweengroup variation tended to exceed the within-group variation. Therefore, subsequent analyses were conducted. The genotypes were grouped into 8 clusters

based on D² value (Table 1, Fig1). Out of eight clusters obtained, cluster II was the largest with 21 genotype, followed by cluster I (16 genotypes), cluster V (11 genotypes), cluster VI (8 genotypes) while cluster III, IV, VII and VIII are the smallest clusters with only a single genotype each. The grouping of genotypes from same source into different clusters as observed in present study may be because of free exchange of breeding material among different regions. Singh *et al.* (2012).

The average intra and inter cluster D² values are presented in (Table 2, Fig 2). Intra cluster D² values ranged from 0.00 (Clusters III, IV, VII and VIII) to 371.74 (Cluster VI) followed by cluster V (209.92); cluster II (111.58); cluster I (96.88). The highest intra cluster distance (371.74) in cluster VI indicates wide genetic variation among the genotypes belonging to these clusters. The III, IV, VII and VIII clusters consisted of only one genotype each hence they lacked intra-cluster distance (0.00).

The inter cluster D² was maximum between clusters V and VI (1651.37) indicating that genotypes in V were far diverse from those of VI. Choosing of genotypes belonging to distant clusters was expected to execute maximum heterosis in crossing and to be used in hybridization program for obtaining a wide spectrum of variation among the segregants. The least distance was observed between cluster IV and VII (94.06) which indicated genotypes included in them were closely related (Table 2).

The cluster wise mean values for 17 characters were presented in Table 3. These are helpful to assess the superiority of clusters during the improvement of characters through hybridization programme. The cluster mean values showed a wide range of variation for majority of the characters undertaken in the present study. The diversity was also supported by the appreciable amount of variation among the cluster means

for different characters. It is observed that cluster III as test weight, grain length, grain L/B ratio and harvest index and cluster VIII exhibited highest mean values for days to maturity, flag leaf length, flag leaf area, number of filled grains per panicle and SCMR, hence selection of this genotype for direct use may be beneficial. Whereas cluster V had highest mean values for Days to 50% flowering, flag leaf width and grain yield per plant. Cluster grains per panicle and grain width. Cluster IV exhibited highest mean value for Panicle length. Therefore, hybridization between the selected genotypes from well as cluster VIII had recorded highest mean values VII had highest mean values for plant height, ill filled for most of the characters. Cluster III exhibited highest mean values for number of productive tillers per plant, divergent clusters is essential to judiciously combine all he targeted traits.

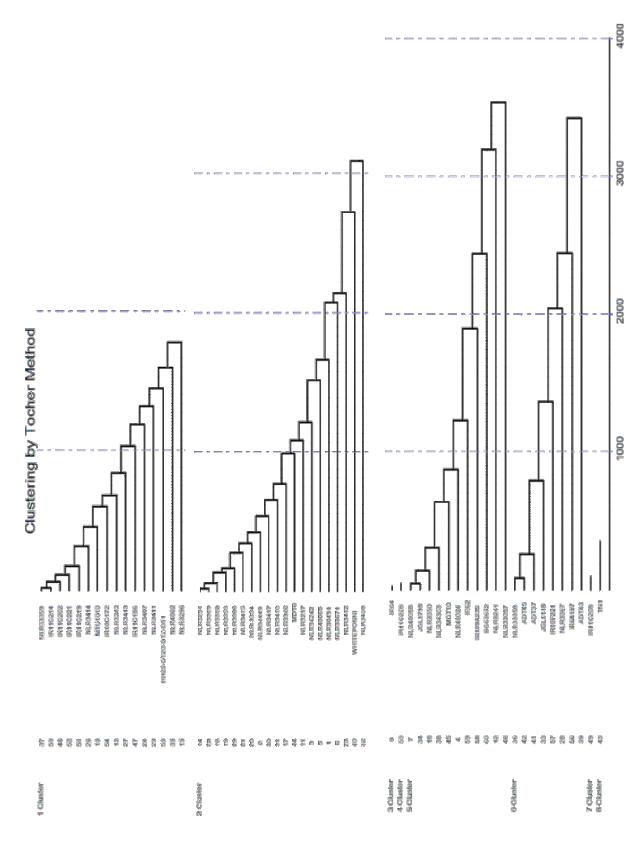

Fig 1a. Dendrogram showing relationship among 60 Ricegenotypes in eight clusters based on Mahalanobis' D2 values

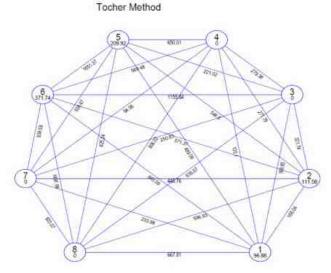

Fig 1b. Intra and inter-cluster distance of 60 Ricegenotypes in eight clusters based on Tocher's method

Contribution of different quality characters to total divergence is presented in Table 4. The trait days to maturity (35.99) showed maximum contribution towards genetic divergence followed by test weight (20.17), flag leaf width (10.68), flag leaf length (6.72), Days to 50% flowering (6.10), grain yield per plant (5.42), grain width (3.56), Panicle length (2.66), harvest index (1.81), plant height (1.69), ill filled grains per panicle (1.58), SCMR (1.19), grain length (1.19), flag leaf area (0.51), number productive tillers per plant (0.40), number of filled grains per panicle (0.28) and grain L/B ratio (0.06).

Out of 17 characters studied the maximum contribution (79.66%) towards total divergence is by 5 characters only. They are days to maturity, test weight, flag leaf width, flag leaf length, Days to 50% flowering. These characters should be taken into consideration while selecting parents for hybridization. On the other hand low contributing characters towards total genetic diversity were grain L/B ratio, productive tiller per plant, number of filled grains per panicle and flag leaf area.

CONCLUSION

It is well known that crosses between divergent parents usually produce greater heterotic effect than between closely related ones. Considering the importance of genetic divergence, the present study indicated that parental lines selected from Cluster V (NLR 40058, JGL 1798, NLR 3350, NLR 34303, MDT 10, NLR 40024, IR 62, IR 109A235, BG 63672, NLR 3241 and NLR 33057) and Cluster VI (NLR 33358, ADT 45, ADT 37, JGL 1118, IR 10F221, NLR 3367, IR 64197 and ADT 43) followed by Cluster VI (NLR 33358, ADT 45, ADT 37, JGL 1118, IR 10F221, NLR 3367, IR 64197 and ADT 43) and Cluster VIII (TN 1) could be used in crossing programmes to achieve desired segregants.
