Department of Soil Science, Achartya N G Ranga Agricultural University, S.V. Agricultural College, Tirupati-517502, Andhra Pradesh, India

#### ABSTRACT

Assessment of soil properties and nutrient status is essential for addressing issues of soil health through which one can guide for maintaining sustainable crop productivity. In view of this, soil samples were collected from selected villages under different mandals of Chittoor district to assess macronutrients and micro nutrients status. A total of 225 soil samples (0-15 cm depth) were collected from groundnut-groundnut cropping system, groundnut-Pigeon pea cropping system, paddy-groundnut cropping system, fallow-paddy cropping system, sugarcane-sugarcane cropping system, perennial fodder system, tomato mono cropping system and mango orchards. The results revealed that highest available nitrogen, phosphorus, potassium and sulphur was found in the groundnut-Pigeon pea cropping system, respectively, whereas the lowest nitrogen, potassium and sulphur was recorded in fallow-paddy cropping system. The available phosphorus was found to be low in groundnut-groundnut cropping system. The highest available calcium, magnesium and DTPA extractable Zn, Cu, Fe and Mn was found in perennial fodder system whereas, lowest Ca and Mg were noticed in groundnut-groundnut cropping system. The Astractable micronutrients viz., Zn, Cu, Fe and Mn were observed under fallow paddy cropping system.

# **Keywords:***Cropping system, DTPA extractable nutrients and production, soil health*

Soil testing is often employed to determine the available nutrient status and nutrient supplying power of soil, which aids in the development of cost-effective nutrient management practices that serves as a foundation for amendments and sound fertilizer recommendations, leading to long-term agriculture production through the adoption of good agronomic management practices by farmers in the study area. Macronutrients (N, P, K, S, Ca and Mg) and micronutrients (Zn, Fe, Cu, Mn) are very important soil elements that controls fertility and productivity of a particular soil. Soil fertility is one of the important factors controlling crop yields and soil characterization in relation to evaluation of soil fertility of an area or a region is an important aspect in the text of sustainable production (Prasad et al., 2020b). In present context, maintaining soil fertility is a key problem in Indian agriculture, especially under the country's rapidly growing population in recent decades. Knowing crop nutrition demand and soil nutrient supplying power determines the amount of fertilizer supplementation. Inadequate fertilizer management resulted in the formation of multinutrient deficits in Indian soils. It is difficult to increase agricultural productivity and feed the world's rapidly growing population without maintaining soil fertility. Soil analysis and the investigation of micronutrient levels have been key research topics in recent decades. Soil nutrient status information is required for advising individual farmers on fertiliser scheduling and monitoring changes in soil fertility over a period.

#### **MATERIAL AND METHODS**

Chittoor district is a part of Rayalaseema region of Andhra Pradesh. Chittoor district lies extreme South of Andhra Pradesh state approximately between 12°37' to 14°08' North latitude and 78°03' to 79°55' East longitude. The district occupies an area of 15,359 km<sup>2</sup>. The soils in the district constitute red loamy (57%), red sandy (34%) and the remaining 9% is covered by black clay, black loamy, black sandy and red clay. Of the total geographical area of 14.98 lakh ha, nearly 30 per cent (3.9 lakh ha) of the area is under cultivation. Chittoor is at 309m above sea level with a tropical climate. The district is characterized under Southern agro climatic zone of Andhra Pradesh based on soil type, rainfall and altitude. Chittoor district receives an annual rainfall of 918.1 mm. The district has the benefit of receiving rainfall during both the South-West and North-East monsoon periods. While the normal rainfall of the district for the South-West monsoon period is 396.00 mm. The average annual temperature in Chittoor is  $26.5^{\circ}C$  (79.8°F). The temperatures are highest on average in May, at around  $30.9^{\circ}C$  (87.7°F). The lowest average temperature in the year occurs in December, it is around  $22^{\circ}C$  (71.9°F).

Survey was conducted in nine major cropping systems growing area of Chittoor district covering 7 mandals and 225 representative surface soil samples (0-15 cm) were collected from farmer's fields. The collected soil samples were shade dried, ground with a wooden hammer, passed through 2 mm sieve and 0.2 mm sieve (for organic carbon) finally stored in a labelled air tight new poly bag for laboratory analysis. Available nitrogen content in the soils was determined by alkaline potassium permanganate method (Subbiah and Asija, 1956). The available phosphorus in the soil samples was extracted with 0.5 M NaHCO<sub>3</sub> (Olsen's reagent) of pH 8.5 and the phosphorus in the extract was estimated calorimetrically by ascorbic acid method using spectrophotometer at 660 nm (Watanabe and Olsen, 1965). The available phosphorus was expressed as  $P_2O_5$  kg ha<sup>-1</sup> by multiplying the phosphorus (P) with 2.29, Available potassium in the soil samples was extracted with neutral normal ammonium acetate (Jackson, 1973) and determined by using flame photometer (Systronics flame photometer 128) and expressed the results in kg ha<sup>-1</sup>, available sulphur was determined by turbidity method (Hesse, 1971). The turbidity is measured using spectrophotometer at 420 nm wavelength and expressed the results in mg kg<sup>-1</sup>. Available calcium and magnesium was extracted with neutral normal ammonium acetate and determined by titrating with 0.01 N EDTA as per procedure out lined by Jackson (1973) and was expressed in  $cmol(p^+)$  kg<sup>-1</sup>. Available zinc, copper, manganese and iron in the soils were determined in DTPA extract, using atomic absorption spectrophotometer (Lindsay and Norvell, 1978).

#### **RESULTS AND DISCUSSION**

**Primary nutrients:** available N, P<sub>2</sub>O<sub>5</sub>, K<sub>2</sub>O status of soils under different cropping systems were shown in Table 1 and depicted in Figure 1. Results revealed that the available nitrogen, phosphorus and potassium of soils under major cropping systems varied from 105 to 315, 12.96 to 85.37 and 117 to 469 kg ha<sup>-1</sup>, respectively. Significantly the highest available nitrogen (265 kg ha<sup>-1</sup>), available phosphorus (72.02 kg ha<sup>-1</sup>) and available potassium (387 kg ha<sup>-1</sup>) <sup>1</sup>) was observed under groundnut-red gram cropping system, paddy-paddy cropping system and perennial fodder system. The lowest available nitrogen (158 kg ha<sup>-1</sup>) and potassium (237 kg ha<sup>-1</sup>) were observed under fallow-paddy cropping system, while the lowest available phosphorus was observed under groundnutgroundnut cropping system (19.29 kg ha<sup>-1</sup>).

The highest available nitrogen was recorded in groundnut-red gram cropping system. Legume is a natural mini-nitrogen manufacturing factory in the field, they have the ability to fix the atmospheric nitrogen and the farmers by growing these crops can play a vital role in increasing indigenous N production (Ghosh *et al.*, 2017; Patrick *et al.*, 2013; Kumar *et al.*,2019b,2020). The low available N was observed in fallow-paddy cropping system due to poor organic carbon content which was evident from high degree of correlation between available N and soil organic carbon (Pradeep *et al.*, 2006).

The available phosphorus was high under paddy-paddy cropping system due to more use of DAP by farmers in the study area. Lowest was observed in groundnut-groundnut cropping system. Legumes utilize more phosphorus there by depleting the phosphorus content in soils, these results are in accordance with Pandey et al. (2019). Significantly the highest potassium was recorded in perennial fodder system due to high application of potassium fertilizers to paddy crop in the study area. Variation Significantly the highest DTPA extractable zinc (0.81  $mg kg^{-1}$ ), copper (1.71 mg kg^{-1}), iron (7.64 mg kg^{-1}) and manganese system  $(12.19 \text{ mg kg}^{-1})$  of soils was found in perennial fodder system, whereas, the lowest DTPA extractable zinc (0.31 mg kg<sup>-1</sup>), copper (0.38 mg kg<sup>-1</sup>), iron  $(2.51 \text{ mg kg}^{-1})$  and manganese system (5.47 mg kg<sup>-1</sup>) was reported in fallow-paddy cropping system. The highest DTPA extractable micronutrients were found in perennial fodder system compared to

crop fields. Similar results were also identified by Saha *et al.* (2019).

High availability of zinc and copper might be due to the presence of relatively more organic materials will increase its availability by providing soluble complexing agents (Zhang et al. (2011). The accumulation of organic carbon in the surface soils alter the solubility and availability of iron through a chelation effect, thus preventing iron from oxidation and precipitation, increasing iron availability (Prasad and Sakal, 1991). These results were further supported by positive relation of available iron with organic carbon (Higher biological activity and the chelation of organic molecules, which are generated during the decomposition of organic matter left behind after crop harvest, are the causes of the increased Mn availability. These observations were confirmed with the findings of Sarkar et al. (2000), Sarkar et al. (2001).

#### CONCLUSION

Nearly all soils had low levels of available nitrogen, phosphorus and potassium status of the soils under study area was found to be fatty. Available calcium and magnesium was sufficient, whereas, available sulphur and DTPA extractable micronutrients *viz.* Fe, Mn, Zn and Cu were deficient to sufficient in soils under different cropping systems. Based on the nutrient status assessed by soil testing, fertilizer recommendations must be made to assist maintain soil health, which in turn enhances nutrient availability to crops for improved growth and yield enhancement over time. Without soil testing, under or over application of chemical fertilisers causes agricultural soils to degrade over time, resulting in a severe drop in production of crops.
